## 1 The normal consistency factor for the range, $d_2$

### 1.1 The joint pdf of order statistics

**Theorem 1.** Let  $X_1, X_2, \dots, X_n$  be a random sample with continuous cdf  $F(x)$  and pdf  $f(x)$ . Let  $X_{(1)}, X_{(2)}, \dots, X_{(n)}$  be the order statistics of a random sample. Then the joint pdf of  $X_{(i)}$  and  $X_{(j)}$  for  $1 \leq i < j \leq n$  is given by

$$f_{(i,j)}(u, v) = \frac{n!}{(i-1)! \times 1! \times (j-i-1)! \times 1! \times (n-j)!} \times \\ \left[ F(u) \right]^{i-1} f(u) \left[ F(v) - F(u) \right]^{j-i-1} f(v) \left[ 1 - F(v) \right]^{n-j}$$

for  $-\infty < u < v < \infty$ .

*Sketch Proof.* For more details, refer to Theorem 5.4.6 in Casella and Berger<sup>1</sup> or Exercise 6.3-10 in Hogg *et al.*<sup>2</sup>.

The value of  $f_{(i,j)}(u, v)\Delta u\Delta v$  is approximated by  $P(u \leq X_{(i)} < u + \Delta u, v \leq X_{(j)} < v + \Delta v)$  which is the probability that  $i - 1$  random variables are less than  $u$ , one random variable is in  $[u, u + \Delta u)$ ,  $j - i - 1$  random variables are in  $[u + \Delta u, v)$ , random variable is in  $[v, v + \Delta v)$ , and the remaining  $n - j$  random variables are greater than or equal to  $v + \Delta v$ .

Now we have the five subintervals,  $(-\infty, u)$ ,  $[u, u + \Delta u)$ ,  $[u + \Delta u, v)$ ,  $[v, v + \Delta v)$ , and  $[v + \Delta v, \infty)$ , and the probabilities of falling to each of the subintervals are

<sup>1</sup>CASELLA, G./BERGER, R. L. Statistical Inference. 2nd edition. Pacific Grove, CA: Duxbury, 2002.

<sup>2</sup>HOGG, R. V./TANIS, E. A./ZIMMERMAN, D. L. Probability and Statistical Inference. 9th edition. Pearson, 2015.

$F(u)$ ,  $F(u + \Delta u) - F(u)$ ,  $F(v) - F(u + \Delta u)$ ,  $F(v + \Delta v) - F(v)$ , and  $1 - F(v + \Delta v)$ , respectively.

The probability  $P(u \leq X_{(i)} < u + \Delta u, v \leq X_{(j)} < v + \Delta v)$  is obtained by the multinomial distribution and we thus have

$$f_{(i,j)}(u, v) \Delta u \Delta v \approx \frac{n!}{(i-1)! \times 1! \times (j-i-1)! \times 1! \times (n-j)!} \times \\ [F(u)]^{i-1} [F(u + \Delta u) - F(u)] [F(v) - F(u + \Delta u)]^{j-i-1} \times \\ [F(v + \Delta v) - F(v)] [1 - F(v + \Delta v)]^{n-j}.$$

Then we have

$$f_{(i,j)}(u, v) \approx \frac{n!}{(i-1)! (j-i-1)! (n-j)!} \times [F(u)]^{i-1} \times \frac{F(u + \Delta u) - F(u)}{\Delta u} \times \\ [F(v) - F(u + \Delta u)]^{j-i-1} \times \frac{F(v + \Delta v) - F(v)}{\Delta v} \times [1 - F(v + \Delta v)]^{n-j}.$$

In the limit as  $\Delta u \rightarrow 0^+$  and  $\Delta v \rightarrow 0^+$ , we have the result.  $\square$

## 1.2 Transformations of variables

First, we briefly review the transformation of rectangular coordinates  $(x, y)$  to polar coordinates  $(r, \theta)$ . If the function  $f(x, y)$  is defined on the domain  $D$ , then we have

$$\iint_D f(x, y) dx dy = \iint_{D^*} f(r \cos \theta, r \sin \theta) r dr d\theta. \quad (1)$$

This popular transformation is used in statistics to prove that

$$\int_{-\infty}^{\infty} \phi(z) dz = 1, \quad (2)$$

where

$$\phi(z) = \frac{1}{\sqrt{2\pi}} \cdot e^{-z^2/2}.$$

To prove (2), it suffices to show that

$$\int_{-\infty}^{\infty} \phi(x) dx \int_{-\infty}^{\infty} \phi(y) dy = 1,$$

which implies that we need to show

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-(x^2+y^2)/2} dx dy = 2\pi. \quad (3)$$

Using (1), the integral in (3) becomes

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-(x^2+y^2)/2} dx dy = \int_0^{\infty} \int_0^{2\pi} e^{-r^2/2} r dr d\theta.$$

Since

$$\int_0^{\infty} e^{-r^2/2} r dr = \left[ -e^{-r^2/2} \right]_0^{\infty} = 1,$$

we have

$$\int_0^{2\pi} \int_0^{\infty} e^{-r^2/2} r dr d\theta = \int_0^{2\pi} 1 d\theta = 2\pi.$$

Next, we consider the transformation of bivariate continuous-type random variables with a joint pdf  $f(x_1, x_2)$  defined on  $S_X$ . Then it is well known that the probability  $P[(X_1, X_2) \in D]$  is calculated using the double integral

$$P[(X_1, X_2) \in D] = \iint_D f(x_1, x_2) dx_1 dx_2.$$

Consider new random variables,  $Y_1 = u_1(X_1, X_2)$  and  $Y_2 = u_2(X_1, X_2)$  where  $y_1 = u_1(x_1, x_2)$  and  $y_2 = u_2(x_1, x_2)$  have only one-to-one transformations, that is, their inverse transforms exist and are given by  $x_1 = v_1(y_1, y_2)$  and  $x_2 = v_2(y_1, y_2)$ . Then the probability  $P[(X_1, X_2) \in D]$  is also calculated using the double  $y_1$  and  $y_2$

$$P[(Y_1, Y_2) \in D^*] = \iint_{D^*} f(v_1(y_1, y_2), v_2(y_1, y_2)) \cdot |J| dx_1 dx_2.$$

Thus, the joint pdf of  $Y_1$  and  $Y_2$  is given by

$$g(y_1, y_2) = f(v_1(y_1, y_2), v_2(y_1, y_2)) \cdot |J|,$$

where  $(y_1, y_2) \in S_Y$  and  $J$  is the Jacobian determinant of order two

$$J = \det \begin{bmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} \end{bmatrix} = \det \begin{bmatrix} \frac{\partial v_1(y_1, y_2)}{\partial y_1} & \frac{\partial v_1(y_1, y_2)}{\partial y_2} \\ \frac{\partial v_2(y_1, y_2)}{\partial y_1} & \frac{\partial v_2(y_1, y_2)}{\partial y_2} \end{bmatrix}.$$

### 1.3 Distribution of the range

Let  $Z_1, Z_2, \dots, Z_n$  be a random sample from a standard normal distribution with pdf  $\phi(z)$  and cdf  $\Phi(z)$ . For notational convenience, we denote  $X_1 = Z_{(1)}$  and  $X_2 = Z_{(n)}$ . Using Theorem 1, we have the joint pdf of  $X_1$  and  $X_2$

$$f_{(1,n)}(x_1, x_2) = n(n-1) \phi(x_1) \phi(x_2) [\Phi(x_2) - \Phi(x_1)]^{n-2}.$$

The goal is to derive the distribution of the range of the sample,  $X_2 - X_1 = Z_{(n)} - Z_{(1)}$ . Next we consider the new random variables given by  $Y_1 = X_1$  and  $Y_2 = X_2 - X_1$ . Notice that the random variable  $Y_2$  is the *range*. The inverse transforms are easily obtained by  $x_1 = y_1$  and  $x_2 = y_1 + y_2$ . Then, using the Jacobian transformation discussed earlier, the joint pdf of  $Y_1$  and  $Y_2$ , denoted by  $g(y_1, y_2)$ , is given by

$$g(y_1, y_2) = n(n-1) \phi(y_1) \phi(y_1 + y_2) [\Phi(y_1 + y_2) - \Phi(y_1)]^{n-2} |J|,$$

where  $-\infty < y_1 < \infty$ ,  $y_2 > 0$  and

$$J = \det \begin{bmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} \end{bmatrix} = \det \begin{bmatrix} \frac{\partial y_1}{\partial y_1} & \frac{\partial y_1}{\partial y_2} \\ \frac{\partial(y_1 + y_2)}{\partial y_1} & \frac{\partial(y_1 + y_2)}{\partial y_2} \end{bmatrix} = \det \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} = 1.$$

Thus, since the Jacobian determinant is equal to one, the pdf of  $Y_2$  (the range) is just the marginal pdf of  $Y_2$  which is given by

$$\begin{aligned} g_2(y_2) &= \int_{-\infty}^{\infty} g(y_1, y_2) dy_1 \\ &= n(n-1) \int_{-\infty}^{\infty} \phi(y_1) \phi(y_1 + y_2) [\Phi(y_1 + y_2) - \Phi(y_1)]^{n-2} dy_1. \end{aligned} \quad (4)$$

Note that the cdf of  $Y_2$  can be easily obtained by

$$G_2(y_2) = n \int_{-\infty}^{\infty} \phi(y_1) [\Phi(y_1 + y_2) - \Phi(y_1)]^{n-1} dy_1.$$

## 1.4 The $k$ -th moment of the range

Using the pdf of the range in (4), we can obtain the  $k$ -th moment of the range,  $Y_2 = Z_{(n)} - Z_{(1)}$ , by calculating the expectation as follows:

$$\begin{aligned}
 E(Y_2^k) &= \int_0^\infty y_2^k g_2(y_2) dy_2 \\
 &= n(n-1) \int_0^\infty y_2^k \int_{-\infty}^\infty \phi(y_1) \phi(y_1 + y_2) [\Phi(y_1 + y_2) - \Phi(y_1)]^{n-2} dy_1 dy_2 \\
 &= n(n-1) \int_{-\infty}^\infty \int_0^\infty y_2^k \phi(y_1) \phi(y_1 + y_2) [\Phi(y_1 + y_2) - \Phi(y_1)]^{n-2} dy_2 dy_1 \\
 &= n(n-1) \int_{-\infty}^\infty \left\{ \int_0^\infty y_2^k [\Phi(y_1 + y_2) - \Phi(y_1)]^{n-2} \phi(y_1 + y_2) dy_2 \right\} \phi(y_1) dy_1.
 \end{aligned}$$

It should be noted that if we replace  $(y_1, y_2)$  with  $(x, w)$ , then the expression for  $E(Y_2^k)$  is identical to Equation (1) of Harter<sup>3</sup> which is given by

$$E(W^k) = n(n-1) \int_{-\infty}^\infty \left\{ \int_0^\infty w^k [\Phi(x+w) - \Phi(x)]^{n-2} \phi(x+w) dw \right\} \phi(x) dx, \quad (5)$$

where  $W = Z_{(n)} - Z_{(1)}$ .

Clearly, the expression for the  $k$ -th moment of the range requires the evaluation of a complicated double integral. Fortunately, for the case where  $k = 1$  which is the expectation, we can derive an alternative formula involving only a single integral. The derivation of this formula will require the application of three different lemmas which we state and prove below.

**Lemma 1.** *Let  $X$  be a continuous random variable with cdf  $F(x)$ . If  $E(|X|^k)$  exists, then we have*

$$(i) \lim_{x \rightarrow \infty} x^k \{1 - F(x)\} = 0 \quad \text{and} \quad (ii) \lim_{x \rightarrow -\infty} |x|^k F(x) = 0.$$

*Proof.* (i) For  $x > 0$ , we have

$$0 \leq x^k \{1 - F(x)\} = x^k \int_x^\infty dF(t) = \int_x^\infty x^k dF(t) \leq \int_x^\infty t^k dF(t).$$

<sup>3</sup>HARTER, H. LEON Tables of Range and Studentized Range. The Annals of Mathematical Statistics, 31 1960, Nr. 4 <URL: <http://dx.doi.org/10.1214/aoms/1177705684>>.

Now, if we can show that the last term  $\int_x^\infty t^k dF(t) \rightarrow 0$  in the limit as  $x \rightarrow \infty$ , then this will complete the proof because we just showed that  $0 \leq x^k \{1 - F(x)\} \leq \int_x^\infty t^k dF(t)$  for  $x > 0$ . In order to prove that  $\int_x^\infty t^k dF(t) \rightarrow 0$  in the limit as  $x \rightarrow \infty$ , note that we also have

$$\begin{aligned} \int_x^\infty t^k dF(t) &= \int_{-\infty}^\infty |t|^k dF(t) - \int_{-\infty}^x |t|^k dF(t) \\ &= E(|X|^k) - \int_{-\infty}^x |t|^k dF(t). \end{aligned}$$

Since  $E(|X|^k)$  exists and  $\lim_{x \rightarrow \infty} \int_{-\infty}^x |t|^k dF(t) = E(|X|^k)$ , we have

$$\int_x^\infty t^k dF(t) = E(|X|^k) - \int_{-\infty}^x |t|^k dF(t) \rightarrow 0$$

in the limit as  $x \rightarrow \infty$ .

(ii) For  $x < 0$ , we have

$$0 \leq |x|^k F(x) = |x|^k \int_{-\infty}^x dF(t) = \int_{-\infty}^x |x|^k dF(t) \leq \int_{-\infty}^x |t|^k dF(t).$$

Now, if we can show that the last term  $\int_{-\infty}^x |t|^k dF(t) \rightarrow 0$  in the limit as  $x \rightarrow -\infty$ , then this will complete the proof because we just showed that  $0 \leq |x|^k F(x) \leq \int_{-\infty}^x |t|^k dF(t)$  for  $x < 0$ . In order to prove that  $\int_{-\infty}^x |t|^k dF(t) \rightarrow 0$  in the limit as  $x \rightarrow -\infty$ , note that we also have

$$\begin{aligned} \int_{-\infty}^x |t|^k dF(t) &= \int_{-\infty}^\infty |t|^k dF(t) - \int_x^\infty |t|^k dF(t) \\ &= E(|X|^k) - \int_x^\infty |t|^k dF(t). \end{aligned}$$

Since  $E(|X|^k)$  exists and  $\lim_{x \rightarrow -\infty} \int_x^\infty |t|^k dF(t) = E(|X|^k)$ , we have

$$\int_{-\infty}^x |t|^k dF(t) = E(|X|^k) - \int_x^\infty |t|^k dF(t) \rightarrow 0$$

in the limit as  $x \rightarrow -\infty$ . □

**Lemma 2.** Let  $X$  be a continuous random variable with cdf  $F(x)$ . Then we have

$$E(X) = \int_0^\infty [1 - F(x)] dx - \int_{-\infty}^0 F(x) dx \quad (6)$$

$$= \int_0^\infty [1 - F(x) - F(-x)] dx. \quad (7)$$

*Proof.* We have

$$\begin{aligned}
 E(X) &= \int_{-\infty}^{\infty} x dF(x) \\
 &= \int_{-\infty}^0 x dF(x) + \int_0^{\infty} x dF(x) \\
 &= \int_{-\infty}^0 x dF(x) - \int_0^{\infty} x d[1 - F(x)].
 \end{aligned} \tag{8}$$

Using integration by parts (*i.e.*,  $\int u dv = uv - \int v du$ ), we have

$$\int_{-\infty}^0 x dF(x) = \left[ xF(x) \right]_{-\infty}^0 - \int_{-\infty}^0 F(x) dx \tag{9}$$

and

$$\int_0^{\infty} x d[1 - F(x)] = \left[ x\{1 - F(x)\} \right]_0^{\infty} - \int_0^{\infty} [1 - F(x)] dx. \tag{10}$$

Applying Lemma 1 to both (9) and (10), we have

$$\int_{-\infty}^0 x dF(x) = - \int_{-\infty}^0 F(x) dx \tag{11}$$

and

$$\int_0^{\infty} x d[1 - F(x)] = - \int_0^{\infty} [1 - F(x)] dx. \tag{12}$$

Next, we can substitute Equations (11) and (12) into (8), in order to obtain (6). Finally, using a change of integration variable technique, we know that  $\int_{-\infty}^0 F(x) dx = \int_0^{\infty} F(-x) dx$ . Therefore, (6) is equivalent to (7) which completes the proof.  $\square$

It should be noted that Lemma 2 is also valid for discrete random variables.

**Lemma 3.** Let  $X_1, X_2, \dots, X_n$  be a random sample with cdf  $F(x)$ . Let  $F_{(j)}(x)$  denote the cdf of the  $j$ -th order statistic  $X_{(j)}$ . Then we have

$$(i) F_{(n)}(x) = [F(x)]^n \quad \text{and} \quad (ii) F_{(1)}(x) = 1 - [1 - F(x)]^n. \tag{13}$$

*Proof.* (i) Since  $X_{(n)} = \max_{1 \leq i \leq n} X_i$  and  $X_1, X_2, \dots, X_n$  are independent, we have

$$\begin{aligned} F_{(n)}(x) &= P\left[\max_{1 \leq i \leq n} X_i \leq x\right] \\ &= P[X_1 \leq x, X_2 \leq x, \dots, X_n \leq x] \\ &= P[X_1 \leq x] P[X_2 \leq x] \cdots P[X_n \leq x] \\ &= [F(x)]^n. \end{aligned}$$

(ii) Similarly, since  $X_{(1)} = \min_{1 \leq i \leq n} X_i$ , we have

$$\begin{aligned} 1 - F_{(1)}(x) &= 1 - P\left[\min_{1 \leq i \leq n} X_i \leq x\right] \\ &= P\left[\min_{1 \leq i \leq n} X_i > x\right] \\ &= P[X_1 > x, X_2 > x, \dots, X_n > x] \\ &= P[X_1 > x] P[X_2 > x] \cdots P[X_n > x] \\ &= [1 - F(x)]^n. \end{aligned}$$

Thus, we have

$$F_{(1)}(x) = 1 - [1 - F(x)]^n.$$

This completes the proof. □

**Theorem 2.** Let  $X_1, X_2, \dots, X_n$  be a random sample with cdf  $F(x)$ . Then the expectation of the range is given by

$$E[X_{(n)} - X_{(1)}] = \int_{-\infty}^{\infty} \left\{ 1 - [F(x)]^n - [1 - F(x)]^n \right\} dx.$$

*Proof.* Using Lemma 2, we have

$$E[X_{(n)}] = \int_0^{\infty} [1 - F_{(n)}(x) - F_{(n)}(-x)] dx$$

and

$$E[X_{(1)}] = \int_0^{\infty} [1 - F_{(1)}(x) - F_{(1)}(-x)] dx.$$

Applying (13) in Lemma 3 to the integral above, we obtain

$$E[X_{(n)}] = \int_0^\infty \left\{ 1 - [F(x)]^n - [F(-x)]^n \right\} dx$$

and

$$E[X_{(1)}] = \int_0^\infty \left\{ [1 - F(x)]^n dx - 1 + [1 - F(-x)]^n \right\} dx.$$

Thus, we have

$$\begin{aligned} E[X_{(n)} - X_{(1)}] &= \int_0^\infty \left\{ 1 - [F(x)]^n - [F(-x)]^n - [1 - F(x)]^n + 1 - [1 - F(-x)]^n \right\} dx \\ &= \int_0^\infty \left\{ 1 - [F(x)]^n - [1 - F(x)]^n + 1 - [F(-x)]^n - [1 - F(-x)]^n \right\} dx \\ &= \int_0^\infty \left\{ 1 - [F(x)]^n - [1 - F(x)]^n \right\} dx + \int_0^\infty \left\{ 1 - [F(-x)]^n - [1 - F(-x)]^n \right\} dx. \end{aligned}$$

Using the change of the integration variable technique for the last term in the above, we have

$$\int_0^\infty \left\{ 1 - [F(-x)]^n - [1 - F(-x)]^n \right\} dx = \int_{-\infty}^0 \left\{ 1 - [F(x)]^n - [1 - F(x)]^n \right\} dx.$$

It is immediate from this result that we have

$$\begin{aligned} E[X_{(n)} - X_{(1)}] &= \int_0^\infty \left\{ 1 - [F(x)]^n - [1 - F(x)]^n \right\} dx + \int_{-\infty}^0 \left\{ 1 - [F(x)]^n - [1 - F(x)]^n \right\} dx \\ &= \int_{-\infty}^\infty \left\{ 1 - [F(x)]^n - [1 - F(x)]^n \right\} dx, \end{aligned}$$

which completes the proof.  $\square$

It should be noted that the above lemmas and theorems are also valid for non-normal distributions. But, we use the results specifically in the case of the normal distribution. Now suppose that we have a random sample from a *standard* normal distribution,  $Z_1, Z_2, \dots, Z_n$ , and we want to calculate the expectation of the sample range. Then we have

$$E[Z_{(n)} - Z_{(1)}] = \int_{-\infty}^\infty \left\{ 1 - [\Phi(z)]^n - [1 - \Phi(z)]^n \right\} dz.$$

Note that the integrand,  $1 - [\Phi(z)]^n - [1 - \Phi(z)]^n$ , is an even function due to the fact that  $\Phi(-z) = 1 - \Phi(z)$  which allows for the simplification of the expectation:

$$d_2 = E[Z_{(n)} - Z_{(1)}] = 2 \int_0^\infty \left\{ 1 - [\Phi(z)]^n - [1 - \Phi(z)]^n \right\} dz.$$

Thus, the estimator  $(X_{(n)} - X_{(1)})/d_2$  is unbiased for  $\sigma$  if a random sample,  $X_1, X_2, \dots, X_n$ , is from a normal distribution.

If  $X_i$  are from  $N(\mu, \sigma^2)$ , then we have  $R = X_{(n)} - X_{(1)} = \sigma(Z_{(n)} - Z_{(1)})$ , where  $Z_i$  are from  $N(\mu, 1)$ . Note that  $d_3$  is defined by  $\text{Var}(R/d_3) = \sigma^2$ . Thus, using  $\text{Var}(R) = \sigma^2 \text{Var}(Z_{(n)} - Z_{(1)})$ , we have

$$d_3 = \sqrt{\text{Var}(Z_{(n)} - Z_{(1)})} = \sqrt{\text{Var}(W)} = \sqrt{E[W^2] - \{E(W)\}^2},$$

where  $W = Z_{(n)} - Z_{(1)}$ . Then, using (5), we can calculate  $d_3$ .

The values of  $d_2$  and  $d_3$  can be easily calculated using the R programming language and we illustrate these below.

## 2 The bias correction factor for the sample standard deviation, $c_4$

It is well known that the sample variance is unbiased under the normal distribution assumption. That is

$$E[S^2] = \sigma^2,$$

where  $S^2 = \sum_{i=1}^n (X_i - \bar{X})^2 / (n-1)$ . Given that the variance estimate is unbiased, a natural question arises. *Is the sample standard deviation also unbiased?* We already know that, *if* the sample standard deviation is unbiased, then the relation below holds

$$E[S] = \sigma,$$

where  $S = [\sum_{i=1}^n (X_i - \bar{X})^2 / (n-1)]^{1/2}$ . As it turns out, the sample standard deviation is *not* unbiased under the normal distribution assumption but, by calculating the expectation of  $S$  explicitly, we can derive a bias-corrected expression which is unbiased. The derivation follows below.

It is also known that  $(n-1)S^2/\sigma^2$  has the chi-square distribution with  $n-1$  degrees of freedom which is equivalent to the gamma distribution with  $\alpha = (n-1)/2$  and  $\theta = 2$ . Now, it is well known that

$$E[Y^c] = \frac{\Gamma(\alpha + c)\theta^c}{\Gamma(\alpha)}$$

when  $Y$  has the gamma distribution with parameters  $\alpha$  and  $\theta$ . Clearly, for  $c = 1/2$ , we have

$$E[\sqrt{Y}] = \frac{\Gamma(\alpha + 1/2)\sqrt{\theta}}{\Gamma(\alpha)}.$$

Now let  $Y = (n-1)S^2/\sigma^2$  so that  $Y$  has the gamma distribution with parameters  $\alpha = (n-1)/2$  and  $\theta = 2$ . Then using the relation above, we obtain

$$E[\sqrt{(n-1)S^2/\sigma^2}] = \frac{\Gamma(n/2)\sqrt{2}}{\Gamma(n/2 - 1/2)}.$$

We then take the previous expectation and simplify under the square-root on the left hand side of the above equation and obtain

$$\frac{\sqrt{n-1}}{\sigma} \cdot E[S] = \frac{\Gamma(n/2)\sqrt{2}}{\Gamma(n/2 - 1/2)}.$$

But this implies that

$$E[S] = c_4 \sigma$$

where

$$c_4 = \sqrt{\frac{2}{n-1}} \cdot \frac{\Gamma(n/2)}{\Gamma(n/2 - 1/2)}.$$

Thus, the estimator  $S/c_4$  is unbiased for  $\sigma$ .

The bias correction factor  $c_4$  can be easily calculated using the R programming language and we illustrate this below.

## R code implementation for $c_4 = E[S]/\sigma$

### 3 The power function of statistical hypothesis testing

In this section, we perform the two-sided hypothesis testing for  $H_0 : \mu = \mu_0$  versus  $H_1 : \mu \neq \mu_0$ . We assume that  $X_1, X_2, \dots, X_n$  are from the normal with mean  $\mu$  and variance  $\sigma^2$ . This test is well known as  $z$ -test (when  $\sigma$  is known) or  $t$ -test (when  $\sigma$  is unknown) in the statistics literature. For example, see Section 8.3 of Casella and Berger<sup>4</sup>.

#### 3.1 When the variance is known

When the variance  $\sigma^2$  is known, the power function of the  $z$ -test is then given by

$$\begin{aligned} K_z(\mu) &= P\left[\frac{|\bar{X} - \mu_0|}{\sigma/\sqrt{n}} > z_{\alpha/2}\right] \\ &= 1 - P\left[\frac{|\bar{X} - \mu_0|}{\sigma/\sqrt{n}} \leq z_{\alpha/2}\right] \\ &= 1 - P\left[-z_{\alpha/2} \leq \frac{\bar{X} - \mu_0}{\sigma/\sqrt{n}} \leq z_{\alpha/2}\right]. \end{aligned} \quad (14)$$

Notice that  $X_i$  are from  $N(\mu, \sigma^2)$ , not from  $N(\mu_0, \sigma^2)$ . Thus,  $(|\bar{X} - \mu|)/(\sigma/\sqrt{n})$  is distributed as the standard normal distribution,  $N(0, 1)$ , but  $(|\bar{X} - \mu_0|)/(\sigma/\sqrt{n})$  is not.

We rewrite the power function in (14) by

$$\begin{aligned} K_z(\mu) &= 1 - P\left[-z_{\alpha/2} + \frac{\mu_0}{\sigma/\sqrt{n}} \leq \frac{\bar{X}}{\sigma/\sqrt{n}} \leq z_{\alpha/2} + \frac{\mu_0}{\sigma/\sqrt{n}}\right] \\ &= 1 - P\left[-z_{\alpha/2} + \frac{\mu_0 - \mu}{\sigma/\sqrt{n}} \leq \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \leq z_{\alpha/2} + \frac{\mu_0 - \mu}{\sigma/\sqrt{n}}\right] \\ &= 1 - P\left[-z_{\alpha/2} - \frac{\mu - \mu_0}{\sigma/\sqrt{n}} \leq \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \leq z_{\alpha/2} - \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right] \\ &= 1 - P\left[-z_{\alpha/2} - \frac{\mu - \mu_0}{\sigma/\sqrt{n}} \leq Z \leq z_{\alpha/2} - \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right], \end{aligned}$$

where  $Z \sim N(0, 1)$ . Thus, we have

$$K_z(\mu) = 1 - \left\{ \Phi\left(z_{\alpha/2} - \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) - \Phi\left(-z_{\alpha/2} - \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) \right\},$$

<sup>4</sup>CASELLA, G./BERGER, R. L. Statistical Inference. 2nd edition. Pacific Grove, CA: Duxbury, 2002.

where  $\Phi(\cdot)$  is the cdf of the standard normal distribution. Using the relation  $\Phi(-z) = 1 - \Phi(z)$ , we can rewrite the above by

$$K_z(\mu) = 1 - \left\{ 1 - \Phi\left(-z_{\alpha/2} + \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) - 1 + \Phi\left(z_{\alpha/2} + \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) \right\}.$$

Therefore, the power function of the  $z$ -test is given by

$$\begin{aligned} K_z(\mu) &= 1 + \Phi\left(-z_{\alpha/2} + \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) - \Phi\left(z_{\alpha/2} + \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) \\ &= 1 - \Phi\left(z_{\alpha/2} + \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right) + \Phi\left(-z_{\alpha/2} + \frac{\mu - \mu_0}{\sigma/\sqrt{n}}\right). \end{aligned}$$

### 3.2 When the variance is not known

**Theorem 3.** Let  $X_1, X_2, \dots, X_n$  be a random sample from a normal distribution with  $\mu$  and variance  $\sigma^2$ . Let  $\bar{X}$  and  $S^2$  denote the sample mean and variance, respectively. Then the following  $t$ -test statistic under the local alternative  $H_1 : \mu = \mu_0 + \delta\sigma/\sqrt{n}$

$$\frac{\bar{X} - \mu_0}{S/\sqrt{n}}$$

has a non-central  $t$ -distribution with  $n - 1$  degrees of freedom and non-centrality  $\delta$ .

*Proof.* Recall the definition of a non-central  $t$ -distribution. Let  $Z \sim N(0, 1)$  and  $V$  has a chi-square distribution with  $r$  degrees of freedom. Suppose that  $Z$  and  $V$  are independent. Then the quotient below has a non-central  $t$ -distribution with  $r$  degrees of freedom and non-centrality  $\mu$ :

$$\frac{Z + \mu}{\sqrt{V/r}}.$$

Let  $V = (n - 1)S^2/\sigma^2$  for convenience. Then  $V$  has a chi-square distribution with  $n - 1$  degrees of freedom. See Theorem 5.3.1 of CASELLA, G./BERGER, R. L.

Statistical Inference. 2nd edition. Pacific Grove, CA: Duxbury, 2002. We have

$$\begin{aligned}\frac{\sqrt{n}(\bar{X} - \mu_0)}{S} &= \frac{\sqrt{n}(\bar{X} - \mu_0)/\sigma}{\sqrt{V/(n-1)}} \\ &= \frac{\sqrt{n}(\bar{X} - \mu)/\sigma + \sqrt{n}(\mu - \mu_0)/\sigma}{\sqrt{V/(n-1)}} \\ &= \frac{Z + \sqrt{n}(\mu - \mu_0)/\sigma}{\sqrt{V/(n-1)}},\end{aligned}$$

where  $Z = (\bar{X} - \mu)/(\sigma/\sqrt{n})$  and  $Z \sim N(0, 1)$ . Thus, under the local  $H_1 : \mu = \mu_0 + \delta\sigma/\sqrt{n}$ , we have

$$\frac{\bar{X} - \mu_0}{S/\sqrt{n}} = \frac{Z + \delta}{\sqrt{V/(n-1)}}.$$

Since  $S^2$  and  $\bar{X}$  are independent,  $V$  and  $Z$  are also independent. This completes the proof.  $\square$

Next, we want to obtain the power function for testing  $H_0 : \mu = \mu_0$  versus  $H_1 : \mu \neq \mu_0$ . Since  $\mu = \mu_0 + \{\sqrt{n}(\mu - \mu_0)/\sigma\} \cdot \{\sigma/\sqrt{n}\}$ , it is immediate upon using Theorem 3 that  $(\bar{X} - \mu_0)/(S/\sqrt{n})$  under  $H_1$  has the non-central  $t$ -distribution with  $\nu = n - 1$  degrees of freedom and non-centrality  $\delta = (\mu - \mu_0)/(\sigma/\sqrt{n})$ .

The critical region for testing  $H_0 : \mu = \mu_0$  versus  $H_1 : \mu \neq \mu_0$  is given by

$$\frac{|\bar{X} - \mu_0|}{S/\sqrt{n}} > t_{\alpha/2}.$$

For convenience, we let  $T_{n-1}(\delta) = (\bar{X} - \mu_0)/(S/\sqrt{n})$ . Then the critical region can be rewritten as  $|T_{n-1}(\delta)| > t_{\alpha/2}$ . Then the power function is given by

$$\begin{aligned}K_t(\mu) &= P(|T_{n-1}(\delta)| > t_{\alpha/2}) \\ &= P(T_{n-1}(\delta) > t_{\alpha/2}) + P(T_{n-1}(\delta) < -t_{\alpha/2}) \\ &= 1 - \Phi_{\nu, \delta}(t_{\alpha/2}) + \Phi_{\nu, \delta}(-t_{\alpha/2}),\end{aligned}$$

where  $\Phi_{\nu, \delta}(\cdot)$  is the cdf of the non-central  $t$ -distribution with  $\nu = n - 1$  degrees of freedom and non-centrality  $\delta = (\mu - \mu_0)/(\sigma/\sqrt{n})$ .

### 3.3 Simulation

As a pilot study, we carried out the Monte Carlo simulation to obtain the empirical power curve of the  $t$ -test for testing  $H_0 : \mu = 1/2$  versus  $H_1 : \mu \neq 1/2$  with the

Figure 1: Empirical power curve along with theoretical power curves.

significance level  $\alpha = 0.05$ . A random sample of size  $n = 5$  was generated from the normal distribution with mean  $\mu$  and  $\sigma = 1$ , where  $\mu$  varies from  $-1$  to  $2$ . This sampling was replicated  $I = 1,000$ . In Figure 1, we plotted the empirical power curve (blue solid line) along with the theoretical power curves of the  $z$ -test (dotted red line) and the  $t$ -test (dotted blue line).

# Critical values of $t$ -distribution.

$$t_{\alpha}(r) = F^{-1}(1 - \alpha) \text{ or } P[T \leq t_{\alpha}(r)] = 1 - \alpha,$$

where  $F^{-1}(\cdot)$  is the inverse CDF of the  $t$  distribution with  $r$  degrees of freedom.
