Talk-1

- Motivation from Control Charts
- We will look at how to pool (combine) location and scale estimators.
- Which methods are preferred? We will provide some proofs (time permitting).

Talk-2

- In Talk-1, we provided some theoretical works under nice conditions (normality and no contamination).
- Some other applications using the method considered in Talk-1.
- What if these conditions are violated?
- Some current works
- Discussions

Motivation from Shewhart-type \bar{X} and S charts

Shewhart-type \bar{X} and S charts

In general, the Shewhart-type control charts are made up of

- UCL: the upper control limit
- **CL**: the center line
- LCL: the lower control limit

This control charts are widely used and well developed when sample sizes are **equal**.

- However, when sample sizes are not equal, there exist only ad hoc methods.
- For the location estimator, two estimators are used.
 Then which one is better?
- Especially for the **conventional** scale estimators, they are all **biased**.

Assumptions

- There are *m* samples (subgroups) but subgroups have **different sizes**.
- Let X_{ij} denote the ith subgroup of size n_i , where i = 1, 2, ..., m and $j = 1, 2, ..., n_i$.
- Assume that X_{ij} are IID normal normal with mean μ and variance σ^2 .

\bar{X} chart

For the *i*th (i = 1, 2, ..., m) subgroup, we have

$$\frac{\bar{X}_i - E(\bar{X}_i)}{\operatorname{SE}(\bar{X}_i)} \stackrel{\bullet}{\sim} N(0,1),$$

where

$$\bar{X}_i = \frac{1}{n_i} \sum_{i=1}^{n_i} X_{ij}.$$

\bar{X} chart — continued

Since $E(\bar{X}_i) = \mu$ and $SE(\bar{X}_i) = \sigma/n_i$, the $CL \pm 3 \cdot SE$ control limits are obtained by setting

$$\frac{\bar{X}_i - \mu}{\sigma/n_i} = \pm 3$$

and solving for \bar{X}_i .

Note that we can obtain the CI if we solve the above for μ .

\bar{X} chart — continued

Solving for \bar{X}_i , the \bar{X} control chart is constructed as follows

$$UCL = \mu + \frac{3\sigma}{\sqrt{n_i}}$$

$$\mathsf{CL} = \mu$$

$$LCL = \mu - \frac{3\sigma}{\sqrt{n_i}}.$$

Issues

- The population parameters μ and σ are **not** known in general.
- Especially, conventional *ad hoc* scale estimators for σ are **biased** when the sample sizes are **not** equal.

S chart

Similarly, we also have

$$\frac{S_i - E(S_i)}{\operatorname{SE}(S_i)} \stackrel{\bullet}{\sim} N(0,1),$$

where S_i is the sample standard deviation with a sample of size n_i . For the $CL \pm 3 \cdot SE$ control limits, we can set up

$$\frac{S_i - E(S_i)}{\operatorname{SE}(S_i)} = \pm 3,$$

where $E(S_i) = c_4(n_i)\sigma$, $Var(S_i) = (1 - c_4(n_i)^2)\sigma^2$, and

$$c_4(n_i) = \sqrt{\frac{2}{n_i - 1}} \frac{\Gamma(n_i/2)}{\Gamma((n_i - 1)/2)}$$

S chart — continued

Using
$$E(S_i) = c_4(n_i)\sigma$$
 and $Var(S_i) = (1 - c_4(n_i)^2)\sigma^2$, we have

$$\frac{S_i-c_4(n_i)\sigma}{\sqrt{1-c_4(n_i)^2}\,\sigma}=\pm 3.$$

Solving for S_i ,

$$UCL = c_4(n_i)\sigma + 3\sqrt{1 - c_4(n_i)^2}\sigma$$

$$CL = c_4(n_i)\sigma$$

$$LCL = c_4(n_i)\sigma - 3\sqrt{1 - c_4(n_i)^2}\sigma.$$

Issue again

• Especially, conventional ad hoc scale estimators for σ are biased.

Location parameter estimation

Two conventional estimators for μ

Montgomery (2013) provided the following location estimators for μ in Equations (6.2) and (6.30) of his book

•
$$\bar{\bar{X}}_A = \frac{\bar{X}_1 + \bar{X}_2 + \dots + \bar{X}_m}{m} = \frac{1}{m} \sum_{i=1}^m \bar{X}_i$$

•
$$\bar{\bar{X}}_B = \frac{n_1 \bar{X}_1 + n_2 \bar{X}_2 + \dots + n_m \bar{X}_m}{N} = \frac{1}{N} \sum_{i=1}^m n_i \bar{X}_i.$$

where $N = \sum_{i=1}^{m} n_i$.

Note that these estimators for μ are unbiased while the *ad hoc* estimates for σ are **biased**.

Issue

Which one of $\bar{\bar{X}}_A$ or $\bar{\bar{X}}_B$ is selected?

The one with the smaller variance!

Location parameter estimation

Theorem 1

If X_{ij} are normal with mean μ and variance σ^2 , then we have

$$\operatorname{Var}(\bar{\bar{X}}_A) \geq \operatorname{Var}(\bar{\bar{X}}_B).$$

Proof.

It is immediate from $\operatorname{Var}(\bar{X}_i) = \sigma^2/n_i$ that we have

•
$$\operatorname{Var}(\bar{\bar{X}}_A) = \frac{1}{m^2} \sum_{i=1}^m \operatorname{Var}(\bar{X}_i) = \frac{\sigma^2}{m^2} \sum_{i=1}^m \frac{1}{n_i} = \frac{\sigma^2}{m} \frac{1}{\bar{n}_h}$$

•
$$Var(\bar{\bar{X}}_B) = \frac{1}{N^2} \sum_{i=1}^m n_i^2 Var(\bar{X}_i) = \frac{\sigma^2}{N^2} \sum_{i=1}^m n_i = \frac{\sigma^2}{N} = \frac{\sigma^2}{m} \frac{1}{\bar{n}_a}$$

where

$$\bar{n}_h = \left(\frac{1}{m} \sum_{i=0}^m n_i^{-1}\right)^{-1} \text{ and } \bar{n}_a = \frac{1}{m} \sum_{i=1}^m n_i.$$

Then we have

$$\frac{\mathrm{Var}(\bar{\bar{X}}_A)}{\mathrm{Var}(\bar{\bar{X}}_B)} = \frac{\bar{n}_a}{\bar{n}_h}.$$

- \bullet \bar{n}_h and \bar{n}_a are harmonic mean and arithmetic mean, respectively.
- $\bar{n}_a \geq \bar{n}_h$.
- Thus, $\operatorname{Var}(\bar{\bar{X}}_A)/\operatorname{Var}(\bar{\bar{X}}_B) \geq 1$ which results in $\operatorname{Var}(\bar{\bar{X}}_A) \geq \operatorname{Var}(\bar{\bar{X}}_B)$.

Which one of $\bar{\bar{X}}_A$ or $\bar{\bar{X}}_B$ is selected?

\bar{X} chart — Recalled

Substituting $\mu = \bar{\bar{X}}_B$, we have

$$UCL = \bar{\bar{X}}_B + \frac{3\sigma}{\sqrt{n_i}}$$

$$\mathsf{CL} = \bar{\bar{X}}_B$$

$$CL = \bar{\bar{X}}_B$$
 $LCL = \bar{\bar{X}}_B - \frac{3\sigma}{\sqrt{n_i}}$.

Thus, we need to estimate σ .

Section 6.3.2 of Montgomery (2013) recommended the followings to estimate σ :

- S_p where $S_p^2 = \sum_{i=1}^m (n_i 1) S_i^2 / (N m)$ (pooled sample variance).
- \bar{S}^* where $\bar{S}^*=\bar{S}/c_4(\bar{n}),\ \bar{S}=\sum_{i=1}^m S_i/m$ and $\bar{n}=\sum_{i=1}^m n_i/m$.

Issues

- Are they unbiased?
- Which one is better?

Note that S_p^2 is unbiased for σ^2 so S_p should underestimate σ . This is easily proved using the Jensen's inequality as follows.

Since \sqrt{T} is concave, we have

$$E(\sqrt{T}) < \sqrt{E(T)}$$
.

With $T = S_p^2$, we have

$$E(\sqrt{S_p^2}) = E(S_p) < \sqrt{E(S_p^2)} = \sqrt{\sigma^2} = \sigma \implies E(S_p) < \sigma.$$

- S_p always underestimate σ ,
- so it is also biased.

Note: whenever S^2 is unbiased for σ^2 , S underestimates σ regardless of an underlying distribution.

Then how about \bar{S}^* ?

Recall \bar{S}^*

$$\bar{S}^* = \frac{\bar{S}}{c_4(\bar{n})},$$

where $\bar{S} = \sum_{i=1}^{m} S_i/m$ and $\bar{n} = \sum_{i=1}^{m} n_i/m$.

It underestimates σ since

$$E[\bar{S}^*] = \frac{\frac{1}{m} \sum_{i=1}^m E[S_i]}{c_4(\bar{n})\sigma} = \frac{\frac{1}{m} \sum_{i=1}^m c_4(n_i)}{c_4(\bar{n})} \cdot \sigma < \sigma.$$

How to prove the above? The claim is to show (the proof is tricky)

$$\frac{1}{m} \sum_{i=1}^{m} c_4(n_i) < c_4(\bar{n})$$

(the proof will be provided later)

As aforementioned, both S_p and \bar{S}^* underestimate σ — biased!

We propose

•
$$\bar{S}_A = \frac{S_1/c_4(n_1) + S_2/c_4(n_2) + \cdots + S_m/c_4(n_m)}{m} = \frac{1}{m} \sum_{i=1}^m \frac{S_i}{c_4(n_i)}$$

•
$$\bar{S}_B = \frac{S_1 + S_2 + \dots + S_m}{c_4(n_1) + c_4(n_2) + \dots + c_4(n_m)} = \frac{\sum_{i=1}^m S_i}{\sum_{i=1}^m c_4(n_i)}$$

Using $E(S_i) = c_4(n_i)\sigma$ under the normality assumption, we see that these are **unbiased** for σ .

Issue

Which one is used?

That is, which one has a smaller variance?

Answer: \bar{S}_B (the proof will be provided later).

It is immediate upon using

$$Var(S_i) = E(S_i^2) - E(S_i)^2 = \sigma^2 \{1 - c_4(n_i)^2\}$$

that we have

$$\operatorname{Var}(\bar{S}_{A}) = \frac{\sigma^{2}}{m^{2}} \sum_{i=1}^{m} \left\{ \frac{1}{c_{4}(n_{i})^{2}} - 1 \right\}$$

and

$$\operatorname{Var}(\bar{S}_B) = \sigma^2 \cdot \frac{\sum_{i=1}^m \left\{ 1 - c_4(n_i)^2 \right\}}{\left\{ \sum_{i=1}^m c_4(n_i) \right\}^2}.$$

In the following section, we will provide several inequalities which are needed for proving it.

In the previous sections, the followings are left to prove

- $\operatorname{Var}(\bar{S}_A) \geq \operatorname{Var}(\bar{S}_B)$
- $E[\bar{S}^*] = \frac{\frac{1}{m} \sum_{i=1}^m E[S_i]}{c_4(\bar{n})\sigma} = \frac{\frac{1}{m} \sum_{i=1}^m c_4(n_i)}{c_4(\bar{n})} \cdot \sigma < \sigma$

Note: \bar{S}^* is recommended for the estimator of σ in Section 6.3.2 of Montgomery (2013).

• To prove the above, it is essential to figure out the behaviors of the c_4 function which is again given by

$$c_4(x) = \sqrt{\frac{2}{(x-1)}} \frac{\Gamma(x/2)}{\Gamma((x-1)/2)}$$

• To this end, we will use the Wallis (1656) and Watson (1959) representations.

Wallis' production formula (Wallis, 1656)

$$\frac{2}{1} \cdot \frac{4}{3} \cdot \frac{6}{5} \cdot \frac{8}{7} \cdot \frac{10}{9} \cdot \frac{12}{11} \cdots \to \infty \text{ (diverges to } \infty \text{)}$$

$$\times \frac{2}{3} \cdot \frac{4}{5} \cdot \frac{6}{7} \cdot \frac{8}{9} \cdot \frac{10}{11} \cdot \frac{12}{13} \cdots \rightarrow 0$$
 (trivially goes to **0**)

$$= \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdot \frac{8}{7} \cdot \frac{8}{9} \cdot \frac{10}{9} \cdot \frac{10}{11} \cdots \rightarrow \frac{\pi}{2}$$

Another version is also given by

$$\frac{1}{\sqrt{\pi(n+\frac{1}{2})}} < \boxed{\frac{1}{2} \cdot \frac{3}{4} \cdot \frac{5}{6} \cdot \cdots \cdot \frac{2n-1}{2n}} < \frac{1}{\sqrt{\pi(n+0)}}$$

The Wallis' production formula can also be rewritten as

$$\boxed{\frac{1}{2} \cdot \frac{3}{4} \cdot \frac{5}{6} \cdot \cdots \cdot \frac{2n-1}{2n}} = \frac{1}{\sqrt{\pi(n+\theta)}},$$

where and $n \ge 1$ and $0 < \theta < \frac{1}{2}$. (NOTE: θ depends on n).

This formula will play a pivotal role in proving the inequalities in this talk.

Note: it is provided in his book, *Arithmetica Infinitorum* in the year of 1656, written in Latin. Recently, Stedall (2004) translated into English.

- Extension of the Wallis' production formula (discrete) by Watson (1959) who used a continuous function.
- $c_4(x)$ function written by the Watson's continuous $\theta(x)$ function
- Using the Watson's $\theta(x)$, we can provide several useful results

Recall

Wallis formula =
$$\left[\frac{1}{2} \cdot \frac{3}{4} \cdot \frac{5}{6} \cdot \dots \cdot \frac{2n-1}{2n}\right] = \frac{1}{\sqrt{\pi(n+\theta)}}$$

where and $n \ge 1$ and $0 < \theta < \frac{1}{2}$ (NOTE: θ depends on n again). We have

$$\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)} = \frac{\sqrt{\pi} \cdot \frac{1}{2}}{1} \cdot \frac{1+\frac{1}{2}}{2} \cdot \frac{2+\frac{1}{2}}{3} \cdot \dots \cdot \frac{n-\frac{1}{2}}{n}$$
$$= \sqrt{\pi} \cdot \left[\frac{1}{2} \cdot \frac{3}{4} \cdot \frac{5}{6} \cdot \dots \cdot \frac{2n-1}{2n} \right] = \frac{1}{\sqrt{n+\theta}}$$

Motivated by the above, Watson (1959) extended to

$$\frac{\Gamma(x+\frac{1}{2})}{\Gamma(x+1)} = \frac{1}{\sqrt{x+\theta(x)}},\tag{1}$$

where $x > -\frac{1}{2}$ and $0 < \theta(x) < \frac{1}{2}$.

(NOTE: x is used instead of n so that $\theta(x)$ is continuous.)

Solving (1) for $\theta(x)$, we have

$$\theta(x) = -x + \frac{\Gamma(x+1)^2}{\Gamma(x+\frac{1}{2})^2} = -x + x \frac{\Gamma(x)\Gamma(x+1)}{\Gamma(x+\frac{1}{2})^2}.$$
 (2)

Since

$$c_4(x)^2 = \frac{1}{(x-1)/2} \frac{\Gamma(x/2)^2}{\Gamma((x-1)/2)^2} = \frac{\Gamma(x/2)^2}{\Gamma((x-1)/2)\Gamma((x+1)/2)},$$

we have

$$c_4(2x+1)^2 = \frac{\Gamma(x+\frac{1}{2})^2}{\Gamma(x)\Gamma(x+1)}.$$
 (3)

Substituting (3) into (2), we have

$$heta(x) = -x + x \cdot rac{1}{c_4(2x+1)^2}$$
 or $extstyle c_4(2x+1) = \sqrt{rac{x}{ heta(x)+x}}$

- We succeeded in rewriting c_4 function using the Watson's $\theta(x)$ function (extended **continuous**-version of **discrete** Wallis product).
- Using the nice properties of $\theta(x)$, we can get several useful results easily.

Properties of $\theta(x)$

- $0 < \theta < \frac{1}{2}$.
- $\theta(x)$ is monotonically decreasing.

Lemma 1

•
$$\sqrt{\frac{x-1}{x}} < c_4(x) < 1$$

Proof.

Recall $\theta(x) = -x + x/c_4(2x+1)^2$ and $0 < \theta(x) < \frac{1}{2}$. Let x = (t-1)/2.

Then we have

$$0 < -x + \frac{x}{c_4(2x+1)^2} < \frac{1}{2} \implies 0 < -\left(\frac{t-1}{2}\right) + \frac{(t-1)/2}{c_4(t)^2} < \frac{1}{2}.$$

Note: $c_4(t)$ is defined on t > 1. Solving the above for $c_4(t)^2$, we have

$$\frac{t-1}{t} < c_4(t)^2 < 1.$$

Lemma 2

- $c_4(x)$ is monotonically increasing
- The function

$$\frac{1}{c_4(x)^2}-1$$

is monotonically decreasing.

Proof.

Proofs are omitted. Please refer to the manuscript.

- Recall: we claim $Var(\bar{S}_A) \geq Var(\bar{S}_B)$.
- To prove this, we need Lemma 3 below.

Lemma 3 (Chebyshev's sum inequality)

If $a_1 \geq a_2 \geq \cdots \geq a_m$ and $b_1 \geq b_2 \geq \cdots \geq b_m$, then

$$m\sum_{i=1}^m a_ib_i \geq \sum_{i=1}^m a_i \cdot \sum_{i=1}^m b_i.$$

Similarly, if $a_1 \leq a_2 \leq \cdots \leq a_m$ and $b_1 \geq b_2 \geq \cdots \geq b_m$, then

$$m\sum_{i=1}^m a_ib_i \leq \sum_{i=1}^m a_i \cdot \sum_{i=1}^m b_i.$$

- The original formula is in an integral form (Chebyshev, 1882).
- Its proof can be found in Chebyshev (1883).

Proof of Chebyshev's sum inequality.

When a_i and b_i are both decreasing, $(a_i - a_j)$ and $(b_i - b_j)$ have the same sign for any i and j. Thus, we have

$$\sum_{i=1}^{m} \sum_{j=1}^{m} (a_i - a_j)(b_i - b_j) \ge 0,$$

which results in

$$2m\sum_{i=1}^{m}a_{i}b_{i}-2\sum_{i=1}^{m}a_{i}\sum_{j=1}^{m}b_{j}\geq0.$$

Next, when a_i are increasing and b_i are decreasing, $(a_i - a_j)$ and $(b_i - b_j)$ have **different signs** or zero for any i and j, Thus, we have

$$\sum_{i=1}^{m} \sum_{i=1}^{m} (a_i - a_i)(b_i - b_i) \leq 0.$$

Recall: we propose

•
$$\bar{S}_A = \frac{S_1/c_4(n_1) + S_2/c_4(n_2) + \cdots + S_m/c_4(n_m)}{m} = \frac{1}{m} \sum_{i=1}^m \frac{S_i}{c_4(n_i)}$$

•
$$\bar{S}_B = \frac{S_1 + S_2 + \dots + S_m}{c_4(n_1) + c_4(n_2) + \dots + c_4(n_m)} = \frac{\sum_{i=1}^m S_i}{\sum_{i=1}^m c_4(n_i)}$$

Theorem 2

We have $Var(\bar{S}_A) \geq Var(\bar{S}_B)$.

Recall: we showed

$$\operatorname{Var}(\bar{S}_A) = \frac{\sigma^2}{m^2} \sum_{i=1}^m \left\{ \frac{1}{c_4(n_i)^2} - 1 \right\} \text{ and } \operatorname{Var}(\bar{S}_B) = \sigma^2 \cdot \frac{\sum_{i=1}^m \left\{ 1 - c_4(n_i)^2 \right\}}{\left\{ \sum_{i=1}^m c_4(n_i) \right\}^2}$$

Sketch proof.

It suffices to show

$$\frac{1}{m^2} \sum_{i=1}^m \left\{ \frac{1}{c_4(n_i)^2} - 1 \right\} \ge \frac{\sum_{i=1}^m \left\{ 1 - c_4(n_i)^2 \right\}}{\left\{ \sum_{i=1}^m c_4(n_i) \right\}^2}$$

- First, let $a_i = c_4(n_i)$ (increasing) and $b_i = 1/c_4(n_i)^2 1$ (decreasing)
- Apply the Chebyshev's sum inequality with a_i and b_i . Then we have an intermediate result.
- Next, let $a_i = c_4(n_i)$ (increasing) and $b_i = 1/c_4(n_i) c_4(n_i)$ (decreasing)
- Apply the Chebyshev's sum inequality again to the above intermediate result with a_i and b_i . Then we have a result.

Recall

Section 6.3.2 of Montgomery (2013) uses

$$\bar{S}^* = \frac{\bar{S}}{c_4(\bar{n})},$$

where $\bar{S} = \sum_{i=1}^m S_i/m$ and $\bar{n} = \sum_{i=1}^m n_i/m$.

Claim: \bar{S}^* underestimates σ since

$$E[\bar{S}^*] = \frac{\frac{1}{m} \sum_{i=1}^m E[S_i]}{c_4(\bar{n})\sigma} = \frac{\frac{1}{m} \sum_{i=1}^m c_4(n_i)}{c_4(\bar{n})} \cdot \sigma < \sigma.$$

It suffices to show

$$\frac{1}{m}\sum_{i=1}^m c_4(n_i) < c_4(\bar{n})$$

Lemma 4

The $c_4(x)$ function is log-concave.

Sketch proof.

Recall the c_4 function which is again given by

$$c_4(x) = \sqrt{\frac{2}{(x-1)} \frac{\Gamma(x/2)}{\Gamma((x-1)/2)}}$$

Thus, we have

$$c_4(x)^2 = \frac{1}{(x-1)/2} \frac{\Gamma(x/2)^2}{\Gamma((x-1)/2)^2} = \frac{\Gamma(x/2)^2}{\Gamma((x-1)/2)\Gamma((x+1)/2)}.$$

Sketch proof – continued.

Taking the logarithm and dividing by two, we have

$$\log c_4(x) = \log \Gamma\left(\frac{x}{2}\right) - \frac{1}{2}\log \Gamma\left(\frac{x-1}{2}\right) - \frac{1}{2}\log \Gamma\left(\frac{x+1}{2}\right).$$

• From Section 11.14 (iv) of Schilling (2005) and Merkle (1996), the second derivative of $\log \Gamma(x)$ can be written as the sum of the series so that we have

$$\frac{d^2}{dx^2}\log\Gamma(x) = \sum_{k=0}^{\infty} \frac{1}{(x+k)^2}.$$
 (4)

Sketch proof — continued.

After tedious algebra, we have

$$\frac{d^2}{dx^2}\log c_4(x) = \sum_{k=0}^{\infty} \frac{1}{(\frac{x}{2}+k)^2} - \frac{1}{2} \sum_{k=0}^{\infty} \frac{1}{(\frac{x-1}{2}+k)^2} - \frac{1}{2} \sum_{k=0}^{\infty} \frac{1}{(\frac{x+1}{2}+k)^2}$$
$$= \sum_{k=0}^{\infty} \frac{-12(x+2k)^2 + 4}{(x+2k)^2(x-1+2k)^2(x+1+2k)^2} < 0.$$

- Thus, we have $\frac{d^2}{dx^2}(-\log c_4(x)) > 0$ so $-\log c_4(x)$ is convex due to Theorem 6.4.6 of Bartle and Sherbert (2011).
- Then $\log c_4(x)$ is concave and $c_4(x)$ is thus log-concave, which completes the proof.

Lemma 5

We have the following inequality

$$\frac{1}{m}\sum_{i=1}^m c_4(n_i) \leq c_4(\bar{n}).$$

Proof.

The log-concavity of $c_4(x)$ from Lemma 4 guarantees that $c_4(x)$ is concave.

Thus, we can apply the Jensen's inequality to $c_4(x)$ and we have

$$\frac{1}{m}\sum_{i=1}^m c_4(n_i) \leq c_4(\bar{n}),$$

where $\bar{n} = \sum_{i=1}^{m} n_i/m$. This completes the proof.

Burr (1969) proposed

$$\bar{S}_C = \frac{\sum_{i=1}^m \frac{c_4(n_i)S_i}{1 - c_4(n_i)^2}}{\sum_{i=1}^m \frac{c_4(n_i)^2}{1 - c_4(n_i)^2}} \text{ and } \bar{S}_D = \frac{S_p}{c_4(N - m + 1)},$$
(5)

where $S_p^2 = \sum_{i=1}^m (n_i - 1) S_i^2 / (N - m)$. Park and Wang (2020) considered

$$\bar{S}_E = \frac{S_N}{c_4(N)},$$

where $S_N^2 = \sum_{i=1}^m \sum_{j=1}^{n_i} (X_{ij} - \bar{X})^2/(N-1)$ and $\bar{X} = \frac{1}{N} \sum_{i=1}^m \sum_{j=1}^{n_i} X_{ij}$. This \bar{S}_E is the UMVUE (uniformly minimum variance unbiased estimator). See Theorem 7.3.23 of Casella and Berger (2002) and Definition 1.6 of Lehmann and Casella (1998).

In summary, we have five choices

$$\bullet \ \bar{S}_A = \frac{1}{m} \sum_{i=1}^m \frac{S_i}{c_4(n_i)}$$

•
$$\bar{S}_B = \frac{\sum_{i=1}^m S_i}{\sum_{i=1}^m c_4(n_i)}$$

•
$$\bar{S}_C = \frac{\sum_{i=1}^{m} \frac{c_4(n_i)S_i}{1 - c_4(n_i)^2}}{\sum_{i=1}^{m} \frac{c_4(n_i)^2}{1 - c_4(n_i)^2}}$$

- $\bar{S}_D = S_p/c_4(N-m+1)$ Note: S_i^2 are pooled, but \bar{X}_i are not pooled.
- $\bullet \ \bar{S}_E = S_N/c_4(N)$

Note: S_i^2 are kind-of pooled and \bar{X}_i are too.

Park and Wang (2020) proved that

- \bar{S}_A , \bar{S}_B , \bar{S}_C , \bar{S}_D , and \bar{S}_E are all unbiased
- $\bullet \ \, \boxed{\mathrm{Var}(\bar{S}_A) \geq \mathrm{Var}(\bar{S}_B) \geq \mathrm{Var}(\bar{S}_C) \geq \mathrm{Var}(\bar{S}_D) \geq \mathrm{Var}(\bar{S}_E)}$

Then, is $Var(\bar{S}_E)$ the best? Maybe not.

Recall: \bar{S}_D and \bar{S}_E

- $\bar{S}_D = S_p/c_4(N-m+1)$ Note: S_i^2 are pooled, but \bar{X}_i are not pooled. Weak (less powerful) under heteroscedasticity (Burr, 1969) (due to pooled S_i^2).
- $\bar{S}_E = S_N/c_4(N)$ Note: S_i^2 are kind-of pooled and \bar{X}_i are too. Weak either under heteroscedasticity or alternative H_1 (out of control) (due to pooled S_i^2 and \bar{X}).

Summary

Summary

- The c_4 function plays a pivotal role in constructing the \bar{X} and S charts.
- With the useful inequalities, we showed that the conventional ad hoc methods are biased, which are used for the \bar{X} and S charts.
- We also proposed new **unbiased** estimators for σ which can be used for various control charts.
- Thus, we can construct **proper** \bar{X} and S charts based on the new **unbiased** estimators.
- The behaviors of the c_4 function are much understood thanks to the connection with **Wallis** product and **Watson** representation.
- \bar{S}_D or \bar{S}_E seem to be the best mathematically, but they may not be preferred over \bar{S}_C . (because we need to consider statistical powers under heteroscedasticity or out-of-control).
 - ⇒ We need to investigate these more thoroughly.
